

Hypothesis Testing and the boundaries between Statistics and Machine Learning

The Data Science and Decisions Lab, UCLA

April 2016

Statistics vs Machine Learning: Two Cultures

Statistical Inference vs Statistical Learning

Statistical inference tries to draw conclusions on the data generation model

Statistical learning just tries to predict Y

**Leo Breiman,
“Statistical Modeling: The Two Cultures,”
Statistical Science, 2001**

Descriptive vs. Inferential Statistics

- **Descriptive statistics**: describing a data sample (sample size, demographics, mean and median tendencies, etc) without drawing conclusions on the population.
- **Inferential (inductive) statistics**: using the data sample to draw conclusions about the population **(conclusion still entail uncertainty = need measures of significance)**
- **Statistical Hypothesis testing** is an inferential statistics approach but involves descriptive statistics as well!

Statistical Inference problems

- **Inferential Statistics problems:**
 - **Point estimation**
 - **Interval estimation**
 - **Classification and clustering**
 - **Rejecting hypotheses**
 - **Selecting models**

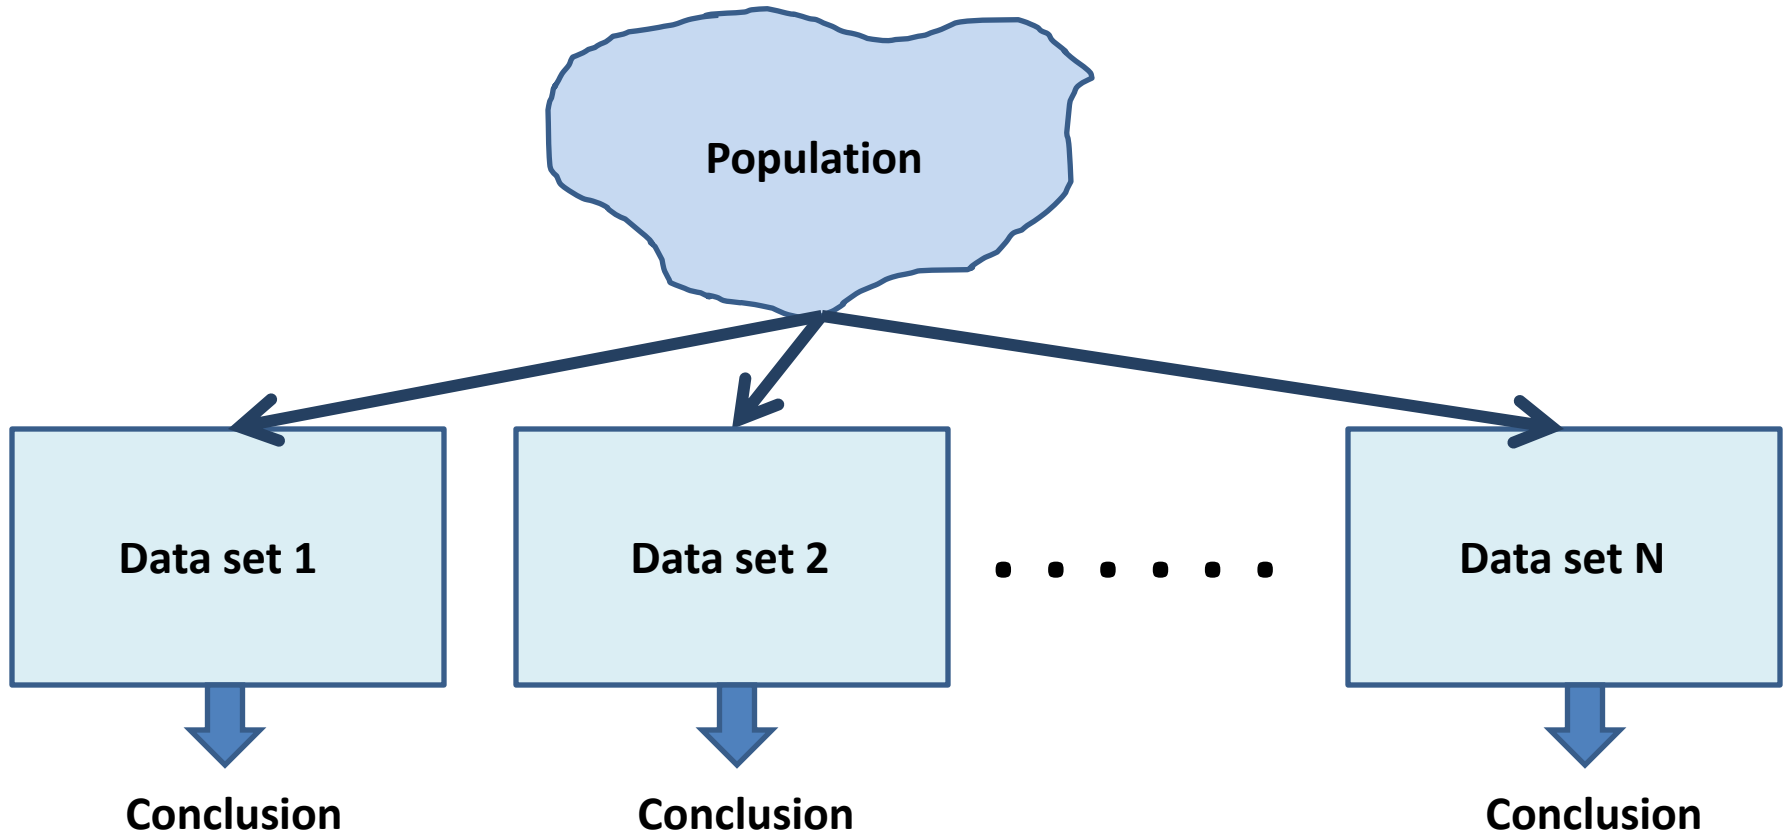

Frequentist vs. Bayesian Inference

- Frequentist inference:
- **Key idea:** *Objective interpretation of probability* - any given experiment can be considered as one of an infinite sequence of possible repetitions of the same experiment, each capable of producing statistically independent results.
- Require that the correct conclusion should be drawn with a given (high) probability among this set of experiments.

Frequentist vs. Bayesian Inference

- Frequentist inference:

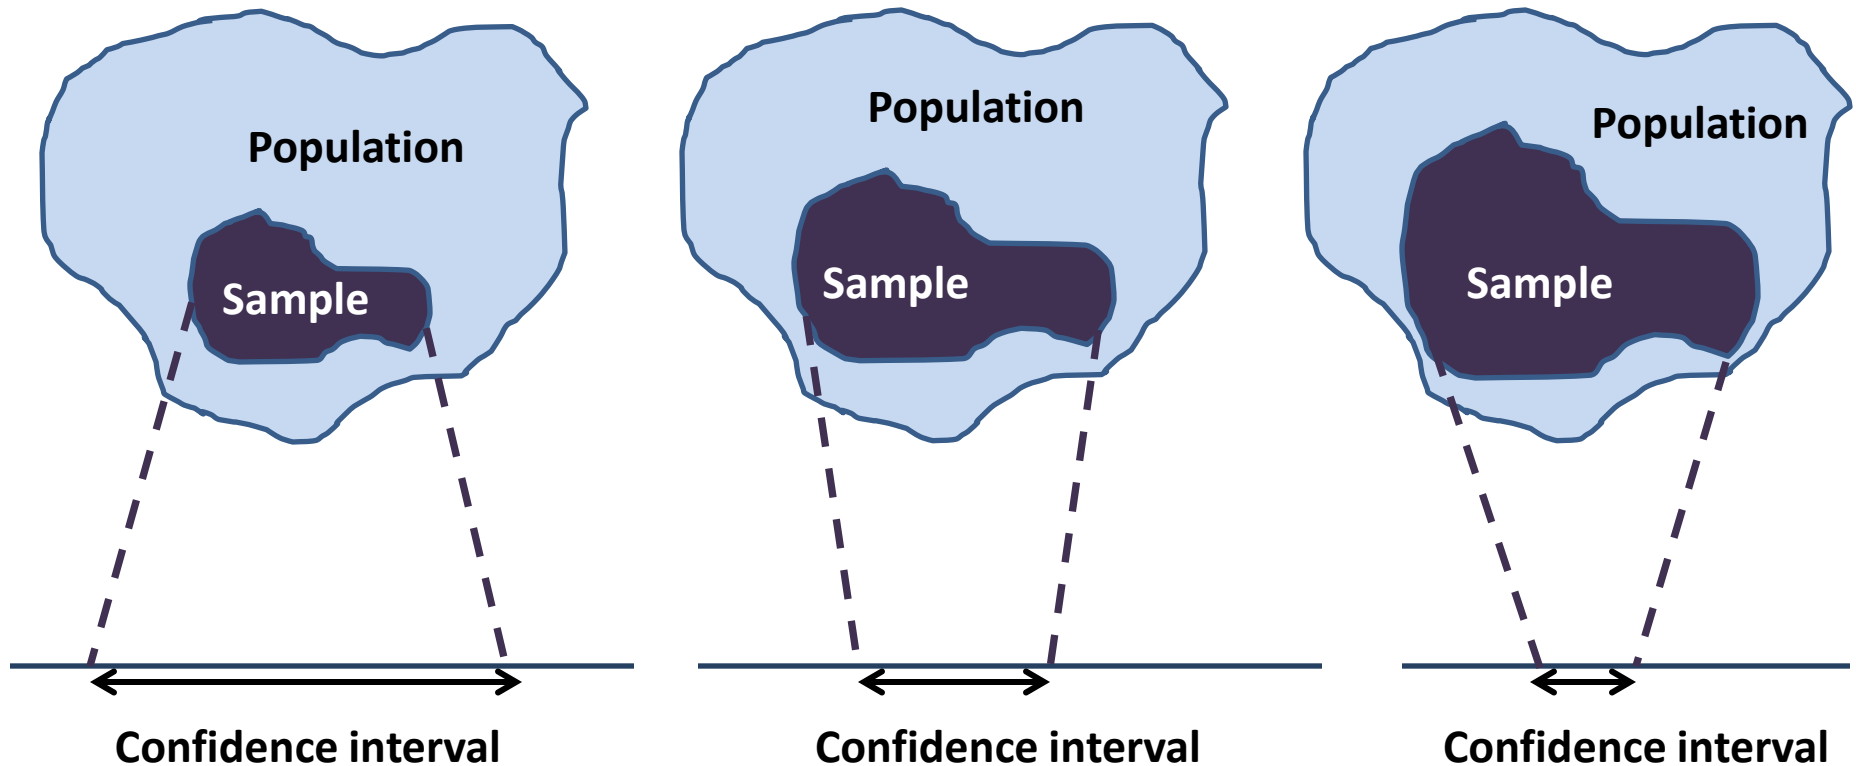

The same conclusion is reached with high probability by resampling the population and repeating the experiment.

Frequentist vs. Bayesian Inference

- Frequentist inference:
- **Measures of significance**: p-values and confidence intervals
- Frequentist methods are **objective**: you can do significance testing or confidence interval estimation without defining any explicit (subjective) utility function.
- Do not need to assume a prior distribution over model parameters, but assume they take fixed, unknown values.

Frequentist vs. Bayesian Inference

- Frequentist inference:
- **Measures of significance:** p-values and confidence intervals

Frequentist vs. Bayesian Inference

- Frequentist inference:

Confidence intervals are random!

The fraction of such intervals that contain the true parameter = confidence level $1-\delta$

Frequentist vs. Bayesian Inference

- Bayesian inference:
- **Key idea:** *Subjective interpretation of probability* – statistical propositions that depend on a posterior belief that is formed having observed data samples. Subjective because it depends on prior beliefs (and utility functions).
- **Measures of significance:** credible intervals and Bayes factors.

Frequentist vs. Bayesian Inference

- Bayesian inference:
- **Credible intervals for parameter estimation**: an interval in the domain of a posterior probability distribution or predictive distribution used for interval estimation
- **Credible intervals vs. Confidence intervals**: Bayesian intervals treat their bounds as fixed and the estimated parameter as a random variable, whereas frequentist confidence intervals treat their bounds as random variables and the parameter as a fixed value.

Frequentist vs. Bayesian Inference

- Bayesian inference: Estimation problems
- **Credible intervals vs. Confidence intervals**

Posterior distribution
(belief)

95% credible interval

$$P(\theta_1 < \theta < \theta_2 | x) = 95\%$$

Random 95% confidence interval

$$P(\hat{\theta}_1(x) < \theta < \hat{\theta}_2(x)) = 95\%$$

$$P(\hat{\theta}_1(x) < \theta < \hat{\theta}_2(x) | x) = 95\%$$

Since parameter is not random,
this probability is either 0 or 1

Frequentist vs. Bayesian Inference

- Bayesian inference: Comparison problems
- **Bayes factors vs. p-values**
- **Bayesian factors are natural alternative to classical hypothesis testing that measure the strength of evidence through “risk ratios”**

$$K = \frac{P(X|H_0)}{P(X|H_1)} = \frac{\int P(\theta_0|H_0)P(X|\theta_0, H_0)d\theta_0}{\int P(\theta_1|H_1)P(X|\theta_1, H_1)d\theta_1}$$

- **Guidelines on the value of K: K<1 negative, K>100 decisive, etc.**

Statistical Hypothesis Testing: Problems

- **Many statistical inference problems involve hypothesis testing:**
- **Examples:**
 - **Which model best fits the data?**
 - **Is treatment X more effective for males than females?**
 - **Is smoking a risk factor for coronary heart diseases?**
 - **Is the chance of a certain intervention being successful depends on a specific feature of the patient?**
 - **Does this subpopulation of patients belong to the same category?**
- **Usually a Yes-No question. Inference = answer this question from a data sample. Understanding the data independent of any specific ML algorithm**

Statistical Hypothesis Testing: the setting

- **Usually we want to test:**
 - 1) Whether two samples can be considered to be from the **same population**.
 - 2) Whether one sample has systematically **larger values** than another.
 - 3) Whether samples can be considered to **be correlated**.

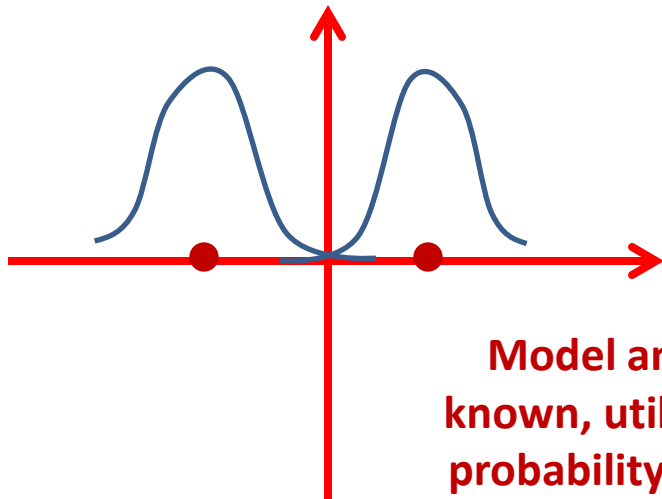

Significance of conclusions: predict the likelihood of an event associated with a given statement (i.e. the hypothesis) occurring by chance, given the observed data and available information.

Testing is usually objective: frequentist significance measures!

Statistical Hypothesis Testing: the setting

Testing is usually objective: frequentist significance measures!

- Complex phenomena (no solid model), inference not necessary associated with specific utility (need objective conclusions)
- e.g. signal detection vs. medical study

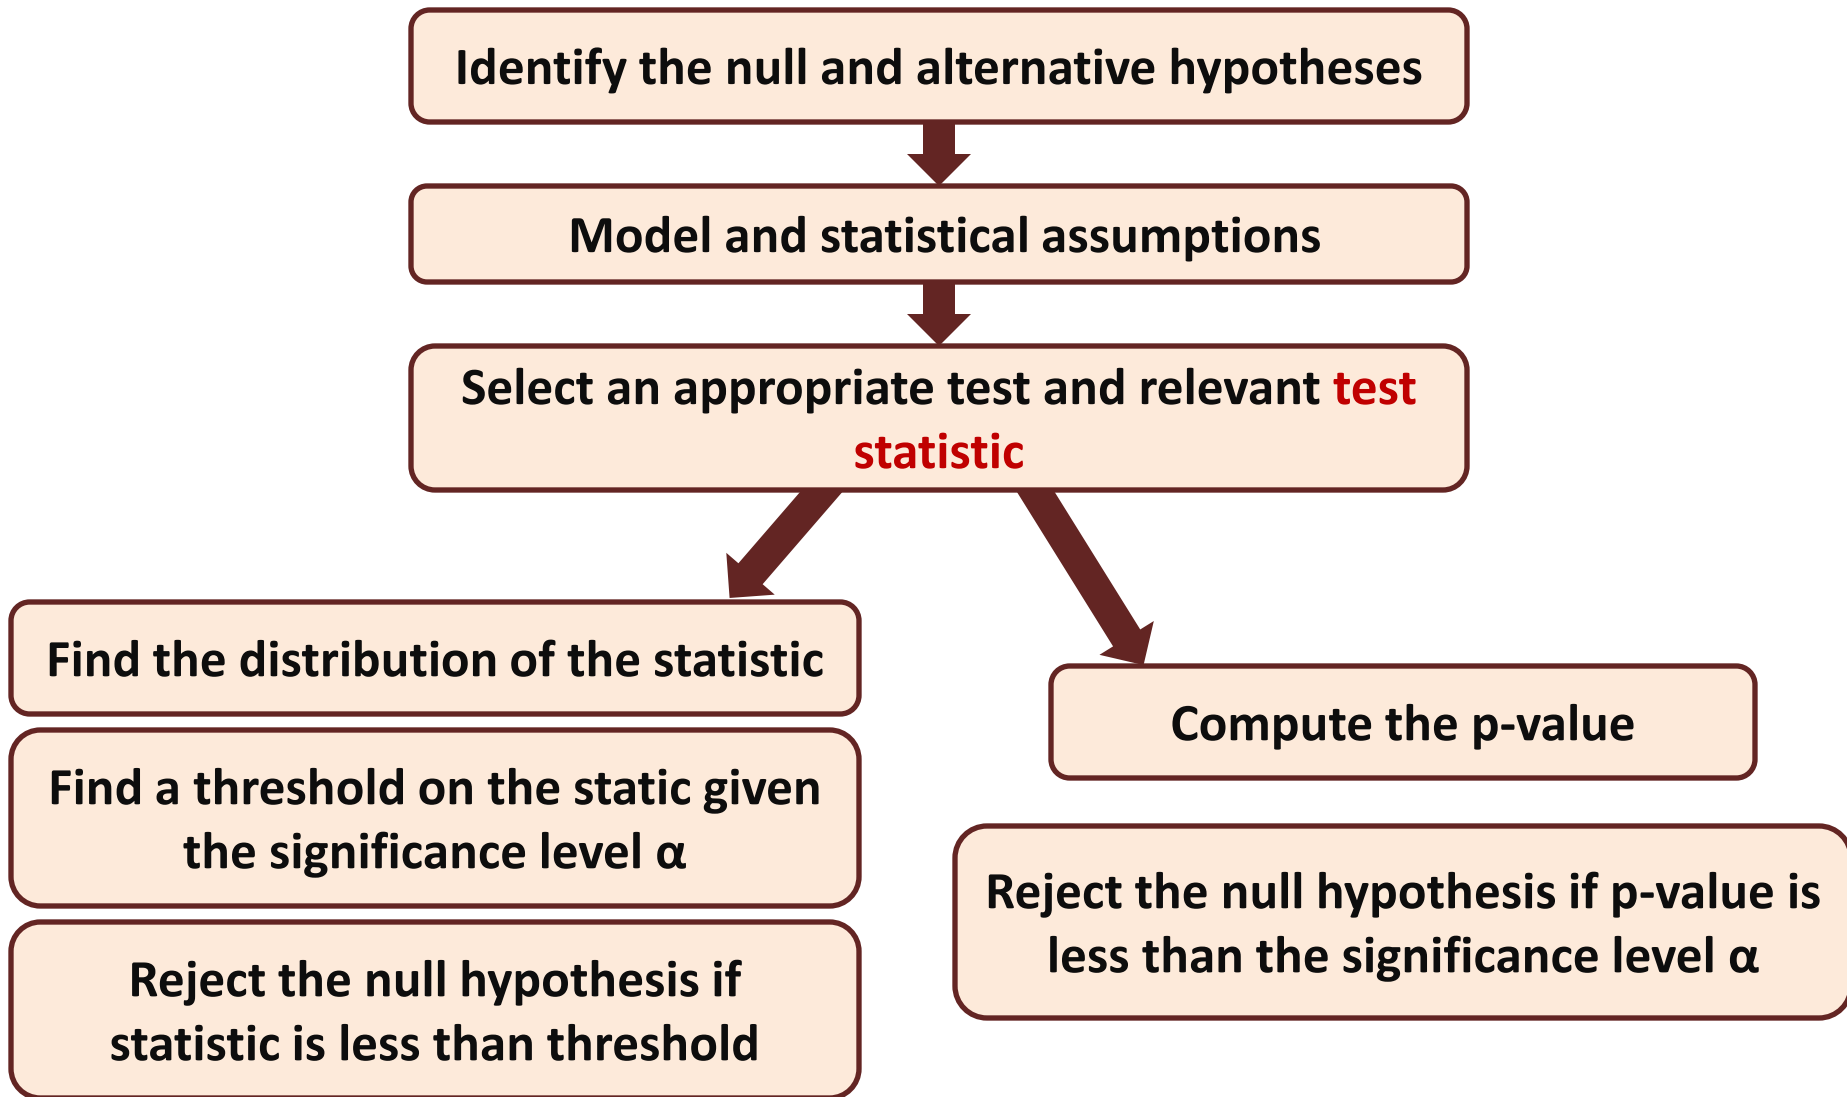

Model and priors known, utility is error probability (Bayesian risk) = Bayesian framework

Effect of smoking?

Complex population, priors may not be easy to construct, no utility = frequentist framework

Statistical Hypothesis Testing: Main steps

Parametric and Nonparametric Hypothesis Testing

Parametric Tests

Assumes a certain **parametric form** of the **underlying distribution**

Less applicability, more statistical power

Nonparametric Tests

Assumes **no specific functional form** on the **underlying distribution**

More applicability, less statistical power

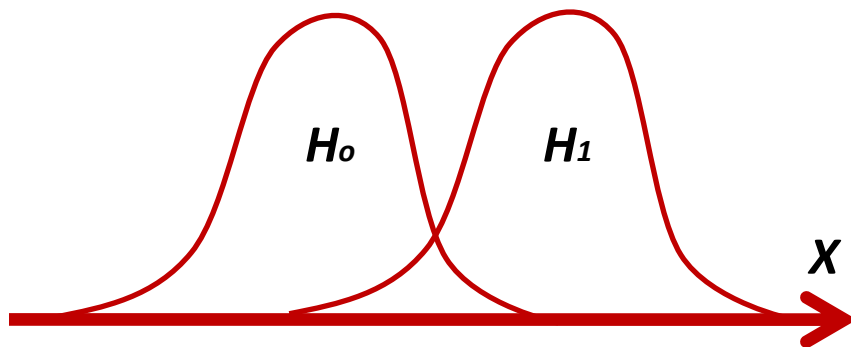

Null Hypothesis test

H_0 : Statement is true
 H_1 : Statement is not true

We want to accumulate enough evidence to reject the null hypothesis.

Parametric and Nonparametric Hypothesis Testing

Parametric Tests

Bayesian framework =
Neyman-Pearson Lemma: Likelihood is
the test statistic, and can be always used
to find a UMP

Frequentist framework =
Can compute closed form p-values

Nonparametric Tests

Distribution-free, but need other
assumptions!

One-sample vs. two-sample tests

One-sample tests

Testing whether a coin is fair

$$H_0 : p = 0.5$$

$$H_1 : p \neq 0.5$$

Two-sample tests

Testing whether two coins have the same probability of heads

$$H_0 : p_1 = p_2$$

$$H_1 : p_1 \neq p_2$$

Measures of significance, type-I and type-II errors, and criteria for rejection

Significance level α : the rate of false positive (type-I) errors, called the **size of the test**.

Significance power $1-\beta$: the rate of false negative (type-II) errors, $1-\beta$ is called the **power of the test**.

$$\alpha = P(\text{reject } H_0 | H_0 \text{ is correct})$$

$$\beta = P(\text{do not reject } H_0 | H_0 \text{ is incorrect})$$

	H_0 is correct	H_0 is incorrect
Reject null hypothesis	false positive type I error (α)	true positive
Fail to reject null hypothesis	true negative	false negative type II error (β)

Measures of significance, type-I and type-II errors, and criteria for rejection

The null hypothesis is rejected whenever the p-value is less than the significance level α

P-value computation

$$p = P(X < x | H_0)$$

Should we pick a parametric or non-parametric test?

	1-sample	2-sample independent	2-sample dependent (paired)
Parametric	t -test	t -test Welch's t -test	paired t -test
Non-parametric	sign test Wilcoxon signed-rank test	median test Mann-Whitney U -test	sign test Wilcoxon signed-rank test

Should we pick a parametric or non-parametric test?

Decide the hypothesis and whether the test is one sample or two-sample

Pick an appropriate parametric test

Test the validity of Assumptions of the parametric test

The t-test

- Assumes that the data is normally distributed: the **Shapiro-Wilk** test is used to check the validity of that assumption
- The test statistic follows a **Student-t distribution**
- **One sample t-test:** test whether the data sample has a mean that is close to a hypothetical mean
- **Two sample t-test:** test whether two data samples have significantly different means

One-sample t-test

- **Null hypothesis:** the population mean is equal to some value μ_0

$$t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}} \quad t \sim \mathcal{T}_{n-1}$$

Independent Two-sample t-test

- **Null hypothesis:** the population mean of two groups are equal

$$t = \frac{\bar{x}_1 - \bar{x}_2}{s_{12} \sqrt{n_1^{-1} + n_2^{-1}}}$$

$$t \sim \mathcal{T}_{n_1+n_2-2}$$

Welch's t-test

- **Null hypothesis:** the population mean of two groups are equal, but does not assume both groups have the same variance

$$t = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

Typical cutoff on the t-statistic

- **Two tailed tests:** the p-values are computed with regard to the two sides of the Student-t distribution, e.g. if significance level is 0.05, then area under each side is 0.025

Typical cutoff on the t-statistic

- Typical significance level is $\alpha = 0.05$, the CDF of Student-t distribution is tabulated

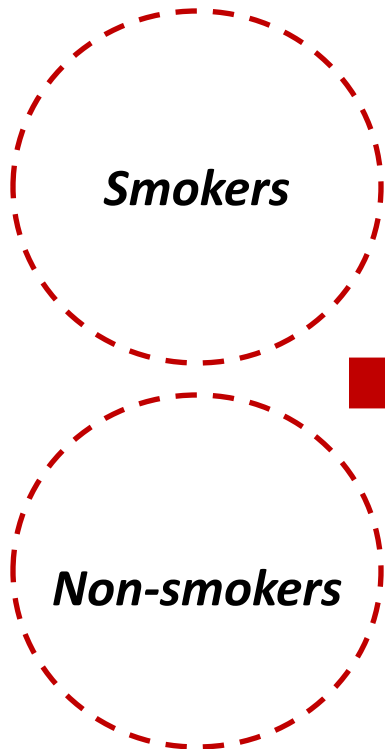

Magic number $t = 2$. (t-statistic cutoff)

df	PROPORTION IN ONE TAIL

				1.298	1.644	1.860
				1.296	1.642	1.857
				1.294	1.640	1.854

Typical cutoff on the t-statistic

- **Typical Statistical Inference in a research study:**
- **Research Question:** Is smoking a risk factor for high blood pressure?

Control demographic features (ages, ethnicities, etc)

$$t = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

Multiple testing

- Testing multiple hypotheses **simultaneously**
- Should we take decision on every hypothesis separately using its **marginal p-value? NO!**
- **Multiple testing matters! We may care about the whole set of tests, need a method to control false discoveries**
- **Example:**
- If $\alpha = 0.05$, and we are doing 100 tests, then the probability of making at least one true null hypothesis is rejected is given by

$$1 - (1 - 0.05)^{100} = 0.994$$

Multiple testing: p-value adjustments and type-I errors control

- For testing M hypotheses, we have a vector of t-statistics and p-values as follows

$$[t_1, t_2, \dots, t_M], [p_1, p_2, \dots, p_M]$$

When people say “adjusting p-values for the number of hypothesis tests performed” what they mean is controlling the Type I error rate.

Type-I error notions for multiple testing

$$\text{FWER} = \mathbb{P} \left(\sum_{i=1}^M \mathbf{1}_{\{t_i > t_i^*\}} \geq 1 \right) \quad \text{FDR} = \mathbb{E} \left[\frac{\sum_{i=1}^M \mathbf{1}_{\{t_i > t_i^*\}}}{M} \right]$$

P-value adjustment methods

Single-step methods

Individual test statistics are compared to their critical values simultaneously

Bonferroni method

Sequential methods

Stepdown methods therefore improve upon single-step methods by possibly rejecting 'less significant' hypotheses in subsequent steps.

Holm's method

Bonferroni method

- Reject any hypothesis with a p-value less than $\frac{\alpha}{M}$
- $\tilde{p} = \min(M p, 1)$
- No assumption on dependency structure, all p-values are treated similarly

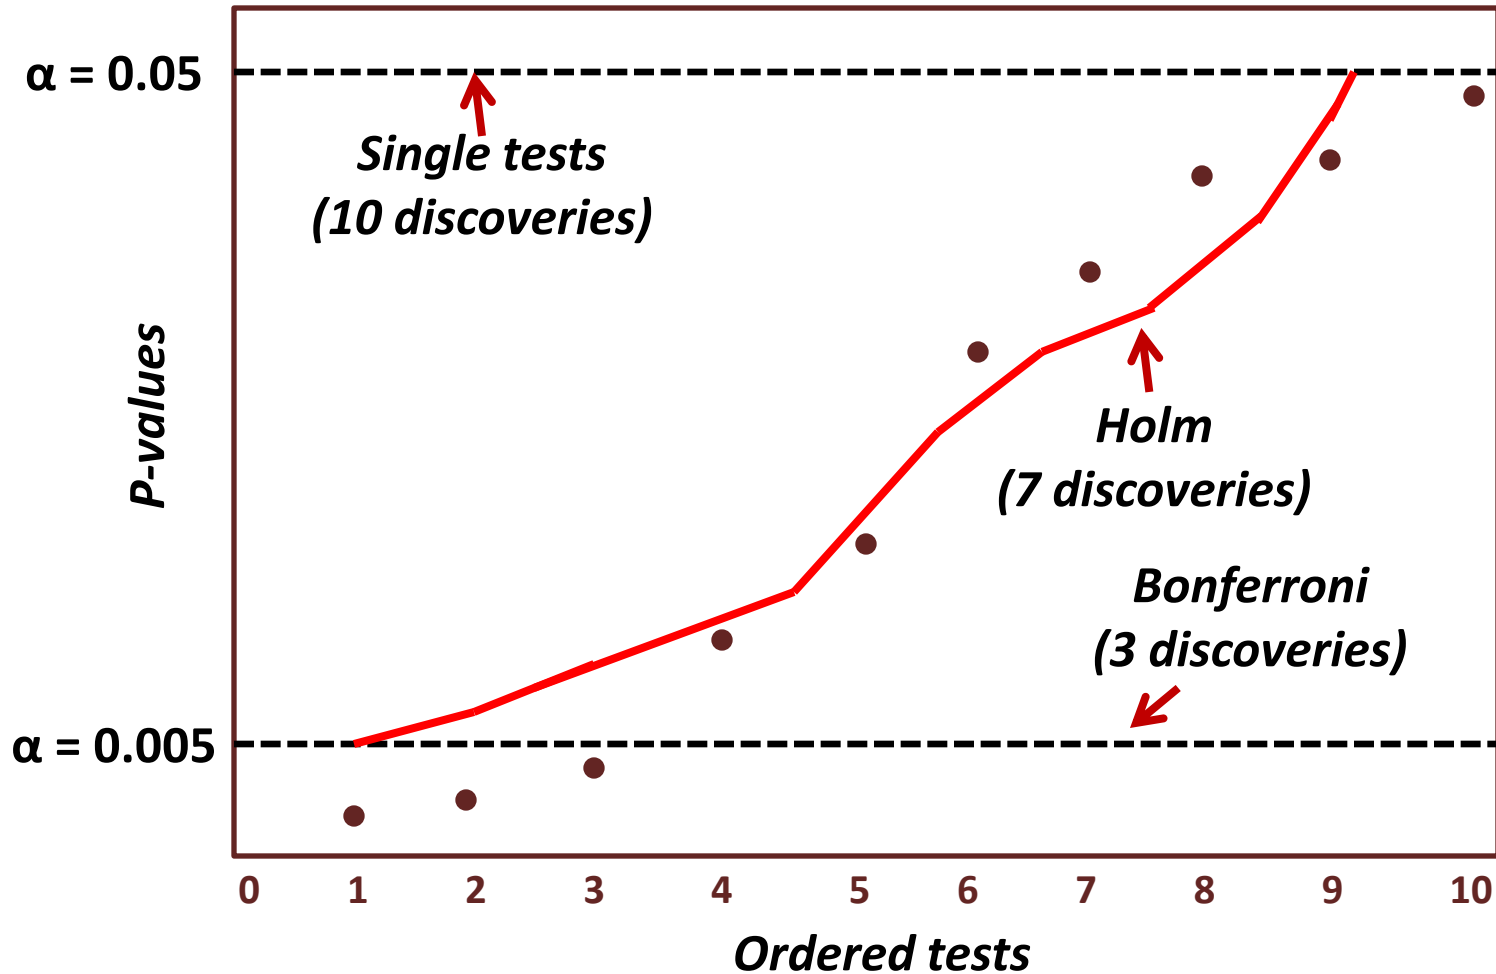

Bonferroni method: criticism

- **Counter-intuitive:** interpretation of finding depends on the number of other tests performed
- **High probability of type-II errors:** not rejecting the general null hypothesis when important effects exist.

**“Bonferroni adjustments are, at best, unnecessary and, at worst, deleterious to sound statistical inference”
Perneger (1998)**

Holm's vs. Bonferroni Discoveries

- For $M = 10$, $\alpha = 0.05$

P. Ioannidis, “Why most published research findings are false?”, PLoS medicine, 2005

**Y. Hochberg, and Y. Benjamini,
“More powerful procedures for multiple
significance testing”, Stat. in Medicine, 1990.**

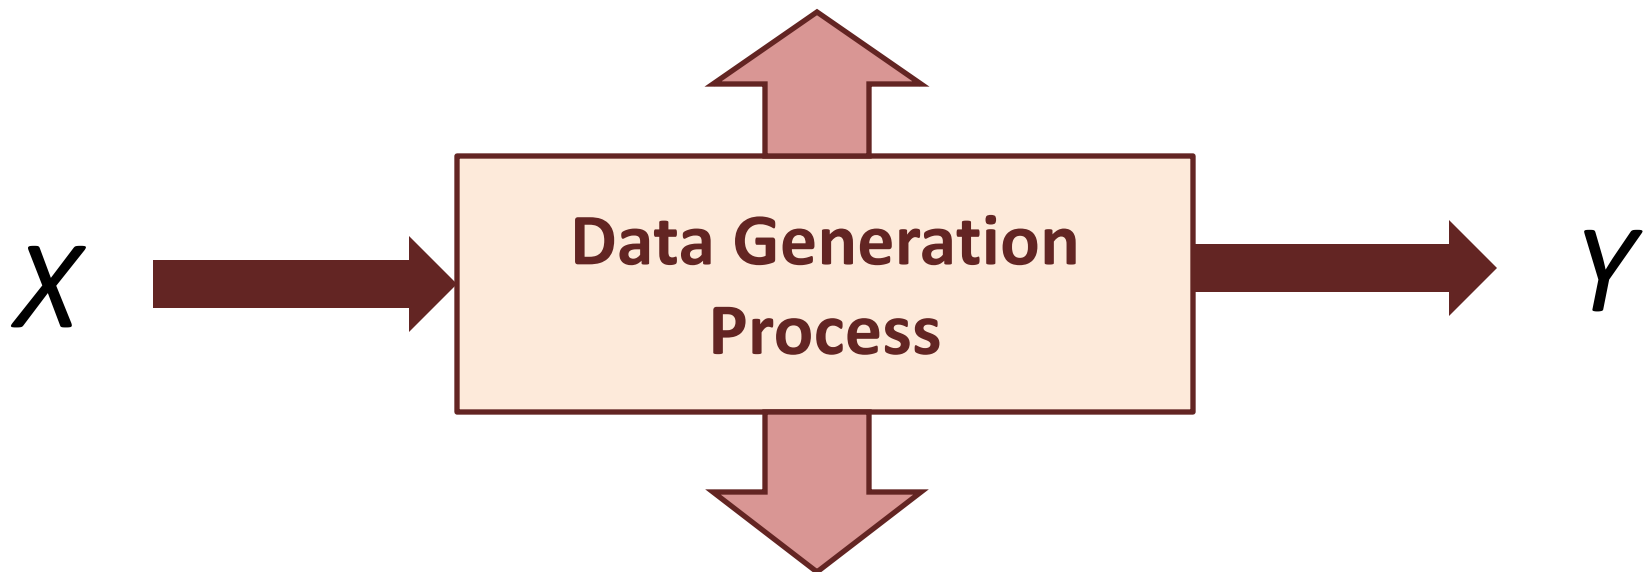

Hypothesis testing or parameter estimation?

- Confidence intervals on t-static instead of p-values if the numeric values are themselves of interest

The marriage of Statistical Learning and Statistical Inference

Statistical inference: draw conclusions about the population in order to select better predictors

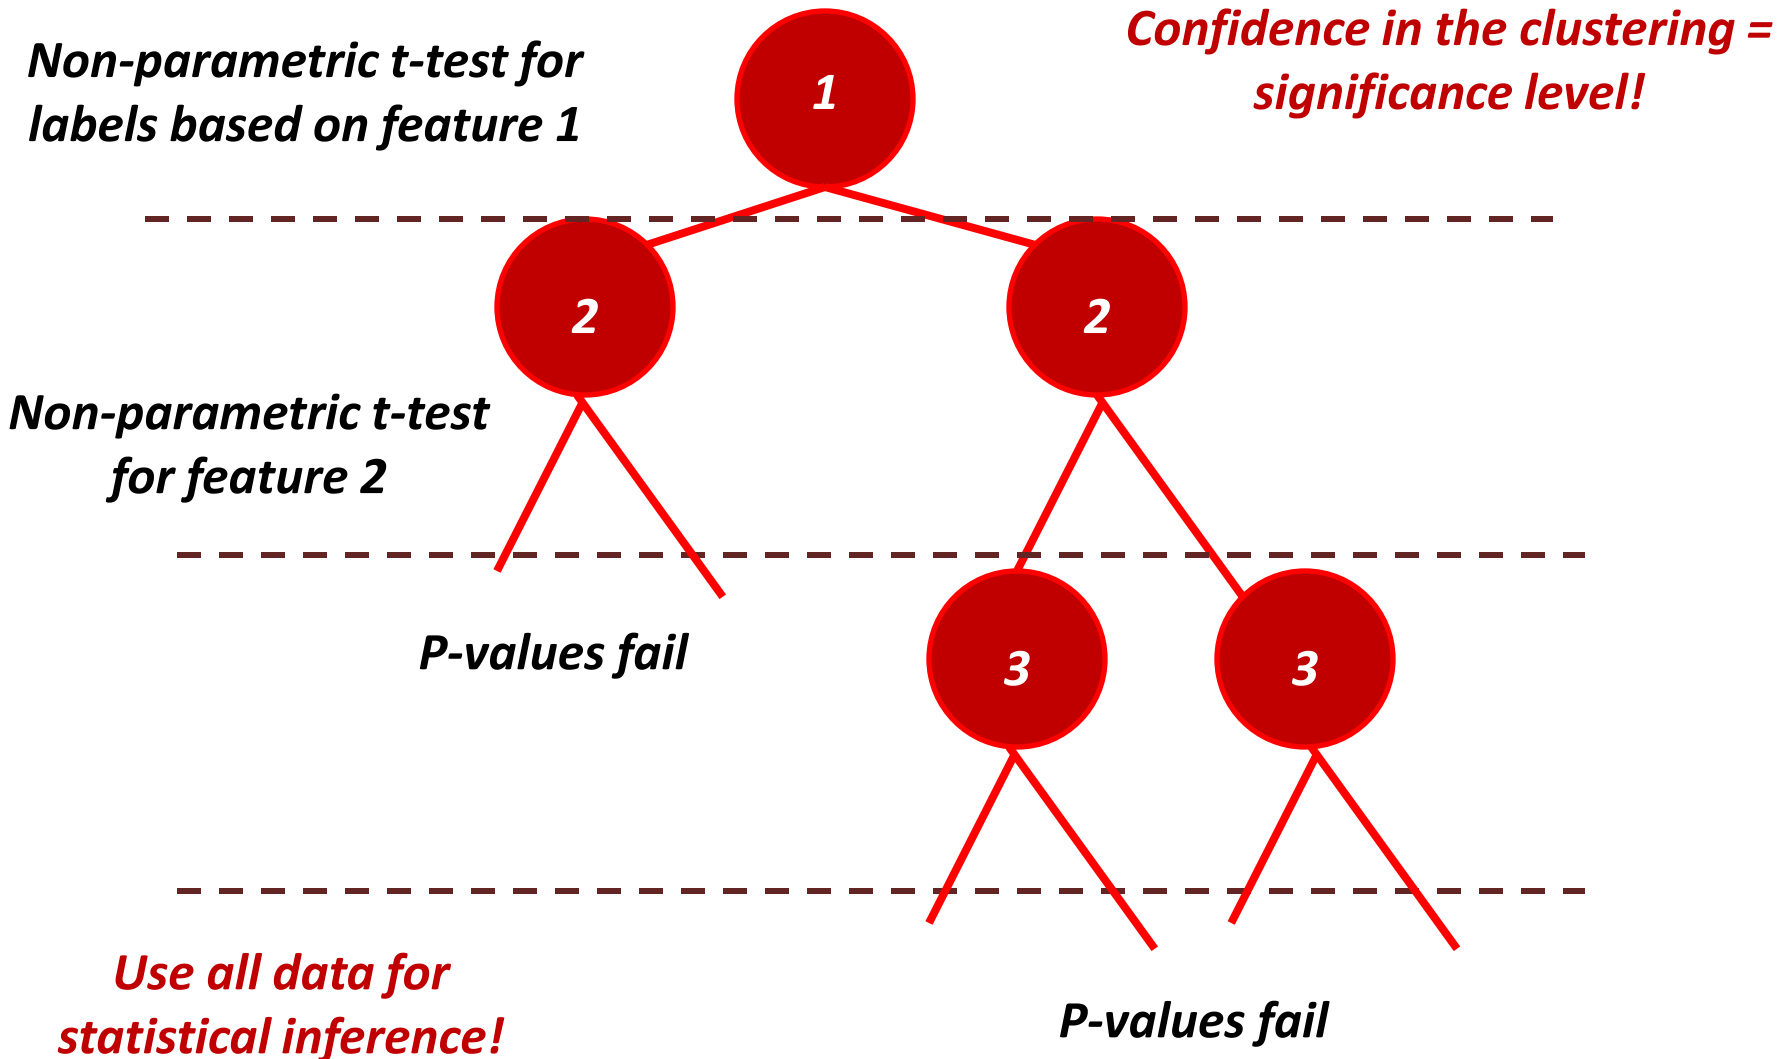

Statistical learning: use inference to build a better predictor for Y

Bringing together Statistical Learning and Statistical Inference

Personalization as a multiplicity of nested tests

- **Key idea: clustering is based on inference of subpopulation properties independent of the classifier and its complexity**
- **Group homogeneous subpopulation together**
- **FWER is now an analog of a PAC confidence bound on the homogeneity of subpopulations!!**
